**Business Intelligence Overview Report: Global Superstore Sales Performance**

## 1. What is Business Intelligence?

Business Intelligence (BI) is the process of collecting, preparing, analyzing, and presenting business data to support better decision-making. BI helps organisations understand their performance by transforming raw information into useful reports, charts, dashboards, and measurable indicators. For example, a retail company can use BI to identify which products generate the highest revenue, which regions are profitable, and where improvements are needed.

## 2. Why organisations use dashboards

Organisations use dashboards to monitor important business activities in one place. Instead of examining thousands of spreadsheet records manually, managers can view key information through charts, tables, and performance indicators. Dashboards help organisations monitor revenue, profitability, customer behaviour, product performance, and geographic differences.

## 3. How dashboards improve decision-making

Dashboards improve decision-making by providing clear and timely information. For example, management can identify regions with declining profits, discover products that generate losses, and understand changes in sales over time. Interactive filters also allow decision-makers to investigate specific regions, product categories, or periods without manually preparing separate reports.

## 4. Business objective of this dataset

The objective of this project is to analyze Global Superstore's historical sales data from 2011 to 2014 using Microsoft Power BI. The analysis aims to evaluate overall sales performance, profitability, customer segments, product categories, and regional differences. The final dashboard will help management identify business strengths, risks, and growth opportunities and develop strategies to improve performance.
